Slide deck available at [course drive/Discussion/Slides/Eric Khiu](#)

# Starter: Matching Pennies

- ▶ Consider a game with two players Alice and Bob
- ▶ Each player has a penny and choose heads or tails
  - ▶ Alice wins the round if both choose the **same** outcome
  - ▶ Bob wins the round if both choose **different** outcome
- ▶ They will play the game for 10 rounds the final winner is whoever **wins the most rounds**
- ▶ Consider the following algorithms:
  - ▶ Here,  $\text{RAND}(S)$  is a function that output a random element in set  $S$

|     |   | Alice      |            |
|-----|---|------------|------------|
| Bob |   | H          | T          |
|     | H | Alice wins | Bob wins   |
|     | T | Bob wins   | Alice wins |

```
ALG1 (roundNum):  
  if roundNum is odd then return H  
  else return T
```

```
ALG2 (roundNum):  
  num ← RAND({0,1})  
  if num is odd then return H  
  else return T
```

**Discuss:** If you were Alice, which algorithm would you choose and why?

# Unit 4: Randomness in Computation

# Motivation: Randomness in computation

- ▶ The algorithms we have seen thus far have been **deterministic**
  - ▶ Execute the **same steps** each time they are run and produce the **same result**
- ▶ If we use deterministic algorithm in Matching Pennies, the opponent would be able to observe the program's strategy once and defeat it every single time thereafter
  - ▶ How to prevent the opponent from predicting our moves? Make moves randomly!
- ▶ In this unit, we consider how **randomness** can be applied to computation
- ▶ We will start with reviewing/ introducing some tools to analyze randomness

# Agenda

- ▶ Tools for analyzing randomized algorithms
- ▶ Markov's inequality
- ▶ Modular arithmetic review (if time)

# Tools for Analyzing Randomness

Warning: This section contains a lot of math

[Course notes](#)

# Expected Values

- ▶ Let  $X$  be a discrete random variable (RV) over the set of events  $\Omega$ , each with some probability in range  $[0,1]$
- ▶ The **expected value** of  $X$  is

$$E[X] = \sum_{\omega \in \Omega} \omega \cdot \Pr[X = \omega]$$

- ▶ Example: Consider a fair 6-sided die with RV  $D$  being the result of the roll.

$$\Pr[D = 1] = \Pr[D = 2] = \dots = \Pr[D = 6] = \frac{1}{6}$$

$$E[D] = 1 \left( \frac{1}{6} \right) + 2 \left( \frac{1}{6} \right) + \dots + 6 \left( \frac{1}{6} \right) = \frac{7}{2}$$

# Linearity of Expectations

- ▶ Let  $X_1$  and  $X_2$  be two RVs and  $X = c_1X_1 + c_2X_2$ , then

$$E[X] = c_1E[X_1] + c_2E[X_2]$$

- ▶ More generally, if we have RVs  $X_1, \dots, X_n$  and  $X = c_1X_1 + \dots + c_nX_n$ , then

$$E[X] = c_1E[X_1] + \dots + c_nE[X_n] = \sum_{i=1}^n c_iE[X_i]$$

- ▶ **Exercise:** Let  $X_1$  be the result of a fair coin toss where  $X_1 = 1$  if heads and  $X_1 = 0$  if tails;  $X_2$  be the results of a fair six-sided die roll. What is the expected value of  $X = X_1 + X_2$ ?

- ▶  $E[X_1] = 0 \left(\frac{1}{2}\right) + 1 \left(\frac{1}{2}\right) = \frac{1}{2}$ ,  $E[X_2] = \frac{7}{2}$  from previous

- ▶ By linearity of expectation,  $E[X] = \frac{1}{2} + \frac{7}{2} = 4$

# Indicator Random Variable

- ▶ An **indicator RV** for an event  $A$  is defined as follows:

$$\mathbb{1}_A = \llbracket A \rrbracket = \begin{cases} 1 & \text{if } A \text{ happens} \\ 0 & \text{otherwise} \end{cases}$$

- ▶ Consider an event  $A$  that happens with probability  $\Pr[A]$ . Let  $X$  be an indicator random variable for  $A$ . What is  $E[X]$ ?

$$E[X] = 1 \cdot \Pr[X = 1] + 0 \cdot \Pr[X = 0] = \Pr[A]$$

- ▶ If  $X$  is a discrete RV, it is sometimes useful to write  $X = X_1 + \dots + X_n$  to compute  $E[X]$

**Discuss:** Intuitively, why do you think this is the case?

- ▶ Linearity of expectation!  $E[X] = E[X_1] + E[X_2] + \dots + E[X_n]$

# Example: Are you a *peak*?

- ▶ Take integers  $1, \dots, n$  and permute them randomly as a sequence  $a_1, \dots, a_n$ . We say  $a_i$  is a *peak* if it is **greater than all previous numbers**, i.e.,  $a_i > a_j$  for all  $j < i$ . For example:

2, 1, 3, 5, 4  $\rightarrow$  three peaks

- ▶ Let  $X$  be the number of peaks in the sequence. Find  $E[X]$ . You may leave your answer as a sum without simplifying it.
  - ▶ Let  $X_i$  be an indicator RV such that  $X_i = 1$  if  $a_i$  is a peak, 0 otherwise
  - ▶ **Obs:**  $\Pr[X_1 = 1] = 1$  (no previous),  $\Pr[X_2 = 1] = 1/2$  (either  $a_2 > a_1$  or  $a_2 < a_1$ )
  - ▶ In general,  $a_i$  is a peak  $\Rightarrow a_i = \max\{a_1, \dots, a_i\}$ , since all  $i$  numbers are distinct and **only one max**, so  $\Pr[X_i = 1] = \Pr[a_i \text{ is } \textit{that} \text{ max}] = 1/i$
  - ▶  $E[X] = E[X_1] + \dots + E[X_n] = \Pr[X_1 = 1] + \dots + \Pr[X_n = 1] = \sum_{i=1}^n \frac{1}{i}$

# Exercise: Increasing Subarray

- ▶ Let  $A$  be an array of length  $n$  of a random permutation of  $n$  distinct integers. Compute the expected number of increasing subarrays in  $A$  of length  $k$ .
  - ▶ Hint: First define an indicator RV that considers whether a particular subarray of length  $k$  is increasing, then determine that probability
  - ▶ Let  $X_i = 1$  if  $A[i, \dots, i + k - 1]$  is increasing and 0 otherwise
  - ▶ Since we only consider subarrays of length  $k$ , set  $X_i = 0$  for  $i = n - k + 2, \dots, n$
  - ▶ For any array of length  $k$ , since all  $k$  numbers are distinct, we have  $k!$  permutations, but **only one is increasing**, so  $\Pr[X_i = 1] = \Pr[A[i, \dots, i + k - 1] \text{ is } \textit{that} \text{ increasing permutation}] = 1/k!$
  - ▶  $E[X] = E[X_1] + \dots + E[X_{n-k+1}] = \sum_{i=1}^{n-k+1} \frac{1}{k!} = \frac{n-k+1}{k!}$

# Recap: Approximation Algorithms

- ▶ We can define how *good* an approximation is in terms of an approximation ratio  $\alpha$ 
  - ▶ Let  $val(y)$  be a function that maps the output of a function to some value
  - ▶ Let  $OPT$  be the value of an optimal solution for some search problem

- ▶ An approximate solution  $y$  is said to be an  **$\alpha$ -approximation** if

$$\alpha \cdot OPT \leq val(y) \text{ for maximization problem}$$

$$val(y) \leq \alpha \cdot OPT \text{ for minimization problem}$$

**Discuss:** Can we prove that the output of a randomized algorithm is an  $\alpha$ -approximation?

- ▶ Yes, but only **in expectation**-sometimes we got unlucky/ lucky and exit the bound!
  - ▶ Use  $E[val(y)]$  instead of  $val(y)$

# Example: 3-painting

- In an undirected graph, a *3-painting* is an assignment of one of three colors to each vertex. (Adjacent vertices do not *necessarily* need to have different colors). Given a 2-painting of an undirected graph, and edge is called *colorful* if its endpoints are **assigned different colors**.

#colorful edges = 5

#colorful edges = 4

# Example: 3-painting

- ▶ In an undirected graph, a *3-painting* is an assignment of one of three colors to each vertex. (Adjacent vertices do not *necessarily* need to have different colors). Given a 2-painting of an undirected graph, an edge is called *colorful* if its endpoints are **assigned different colors**.

- ▶ Consider the following algorithm:

PAINTING( $G=(V,E)$ ):

  for  $v$  in  $V$ :

$num \leftarrow \text{RAND}(\{1,2,3\})$  // uniformly choose between  $\{1,2,3\}$  with prob.  $1/3$  each

    if  $num = 1$  then  $v.\text{color} \leftarrow \text{pink}$

    else if  $num = 2$  then  $v.\text{color} \leftarrow \text{blue}$

    else  $v.\text{color} \leftarrow \text{yellow}$

- ▶ Prove that PAINTING is  **$2/3$  approximation** in expectation.
  - ▶ Hint: First compute  $E[\text{val}(y)]$ , then prove the bound

# Example: 3-painting

```
PAINTING( $G=(V,E)$ ):
```

```
  for  $v$  in  $V$ :
```

```
    num  $\leftarrow$  RAND( $\{1,2,3\}$ ) // uniformly choose between  $\{1,2,3\}$  with prob.  $1/3$  each
```

```
    if num = 1 then  $v.color \leftarrow$  pink
```

```
    else if num = 2 then  $v.color \leftarrow$  blue
```

```
    else  $v.color \leftarrow$  yellow
```

## ► Step 1: Compute $E[val(y)]$

- For each  $e \in E$ , let  $X_e$  be an indicator RV such that  $X_e = 1$  if  $e$  is colorful and 0 otherwise
- For each  $e$ , there are  $3 \cdot 3 = 9$  possible paintings, 3 of them have same colors on both ends (**6 of them have different colors**), so  $\Pr[X_e = 1] = \frac{6}{9} = \frac{2}{3}$
- $E[X] = \sum_{e \in E} E[X_e] = \sum_{e \in E} \Pr[X_e = 1] = \frac{2}{3} |E|$

# Example: 3-painting

```
PAINTING( $G=(V,E)$ ):
```

```
  for  $v$  in  $V$ :
```

```
    num  $\leftarrow$  RAND( $\{1,2,3\}$ ) // uniformly choose between  $\{1,2,3\}$  with prob.  $1/3$  each
```

```
    if num = 1 then  $v.color \leftarrow$  pink
```

```
    else if num = 2 then  $v.color \leftarrow$  blue
```

```
    else  $v.color \leftarrow$  yellow
```

## ► Step 2: Prove bound

► Now we have  $E[val(y)] = \frac{2}{3} |E|$

► Let  $OPT$  be the optimum number of colorful edges. By definition,  $OPT \leq |E|$

► Therefore,  $E[val(y)] = \frac{2}{3} |E| \geq \frac{2}{3} OPT$ , as desired.

# TL; DPA

- ▶ We reviewed/ introduced tools to analyze randomness: expected values, linearity of expectations, and indicator RV
- ▶ It is sometimes useful to express a discrete RV as a sum of indicator RV when computing expectations
- ▶ For randomized algorithm, use  $E[val(y)]$  to prove approximation in expectation

# Markov Inequality

Warning: This section also contains a lot of math

[Course notes](#)

# Starter: Search Algo Optimization

- ▶ Suppose you are optimizing a search algorithm for a large, constantly updating database system. The user **can't wait for more than 1 second in general.**
- ▶ You have the following two options

## Option A

- Average search time: 0.05s
- **Potentially take more than 2s** on a search during high-demand periods

## Option B

- Average search time: 0.15s
- **Rarely take more than 0.6s** on any search even under heady load

**Discuss:** Which one would you choose and why? What additional information you think will help you make the decision?

- ▶  $\Pr[A \text{ takes more than } 1s]$  and  $\Pr[B \text{ takes more than } 1s]$
- ▶ **Obs:** They are both probabilities that **the RV deviates from the expectation by some amount**

# Markov Inequality

- ▶ **Motivation:** Find an **upper bound** on the probability that a random variable  $X$  **deviates from its expected value by some amount**
- ▶ **Markov's Inequality:** Let  $X$  be a **positive** RV and  $a > 0$ , then

$$\Pr[X \geq a] \leq \frac{E[X]}{a}$$

- ▶ Rearranging, we get

$$\Pr[X \geq a \cdot E[X]] \leq \frac{1}{a}$$

# Example: Hash Table

$$\Pr[X \geq a] \leq \frac{E[X]}{a}$$
$$\Pr[X \geq a \cdot E[X]] \leq \frac{1}{a}$$

- ▶ Suppose we have a hash table of size  $n^2$  and a hash function  $h$  that chooses the mapping address uniformly at random from  $0, \dots, n^2 - 1$ .
- ▶ Let  $S = \{s_1, \dots, s_n\}$  be the set of inserted elements and  $X$  be the RV indicating the number of collisions after performing  $n$  insertion.
- ▶ Find an upper bound on the probability that **there is at least one collision** ( $h(s_i) = h(s_j)$ ) after inserting  $n$  distinct elements. (You may use  $\frac{n-1}{2n} < \frac{1}{2}$  for any  $n \in \mathbb{N}$ )

- ▶ First, compute  $E[X]$

$$E[X] = \sum_{\substack{\text{all pairs } (i,j) \\ i \neq j}} \Pr[h(s_i) = h(s_j)] = \sum_{\substack{\text{all pairs } (i,j) \\ i \neq j}} \frac{1}{n^2} = \binom{n}{2} \cdot \frac{1}{n^2} = \frac{n-1}{2n}$$

- ▶ Using Markov's inequality

$$\Pr[X \geq 1] \leq \frac{E[X]}{1} = \frac{n-1}{2n} < \frac{1}{2}$$

# Search Algo Optimization Revisit

$$\Pr[X \geq a] \leq \frac{E[X]}{a}$$
$$\Pr[X \geq a \cdot E[X]] \leq \frac{1}{a}$$

## Option A

- Average search time: 0.05s
- **Potentially take more than 2s** on a search during high-demand periods

## Option B

- Average search time: 0.15s
- **Rarely take more than 0.6s** on any search even under heady load

- Let  $A$  be the search time using option A and  $B$  be the search time using option B. Using Markov's inequality and  $a = 1$ , we have

$$\Pr[A \geq 1] \leq 0.05 \quad \text{and} \quad \Pr[B \geq 1] \leq 0.15$$

**Discuss:** Does this result change your decision?

- The upper bounds of the chance of option A taking at least 1 second is lower than that of option B- **maybe A is better?**
- **WAIT:** We haven't considered the "rarely take more than 0.6s"! Who knows  $\Pr[B \geq 1]$  is actually 0.0001?
- **Takeaway:** Markov's inequality is a **weak** bound, but still applicable to many cases

# “Reverse” Markov Inequality

- ▶ We can also find the **lower bound** on the probability that a RV  $X$  deviates from its expected value by some amount, if we know some upper bound for  $X$

- ▶ If  $X$  is positive RV that is never larger than  $B$  and  $a < B$ , then

$$\Pr[X > a] \geq \frac{E[X] - a}{B - a}$$

- ▶ **Example:** Suppose we have a biased coin where  $\Pr[H] = 0.3$ . Find a lower bound on the probability that there are strictly more than 10 heads after 100 tosses.

- ▶ Let  $X$  be the number of heads after 100 tosses

- ▶ We have  $E[X] = 0.3 \cdot 100 = 30$  and  $B = 100$ , so

$$\Pr[X > 10] \geq \frac{30 - 10}{100 - 10} = \frac{2}{9}$$

# TL; DPA

- ▶ Markov's inequality gives upper bound on the probability that a positive RV deviates from its expected value by some amount
- ▶ It is a weak bound, but applicable in many cases
- ▶ “Reverse” Markov's inequality gives a lower bound

# Modular Arithmetic Review

Warning: This section still contains a lot of math

[Course notes](#)

# Modular Arithmetic Review

- ▶ Let,  $a, b, n$  be integers
- ▶ **Definition:**  $a \bmod n$  is the **remainder** of  $a$  when divided by  $n$ 
  - ▶  $a \bmod n$  is a unique value in  $\mathbb{Z}_n = \{0, \dots, n-1\}$
- ▶ **Definition:**  $a$  and  $b$  are **congruent modulo  $n$** , written as  $a \equiv b \pmod{n}$  if
  - ▶  $a \bmod n = b \bmod n$ , or equivalently,
  - ▶  $\exists k \in \mathbb{Z}$  such that  $a = b + kn$ , or equivalently
  - ▶  $a - b$  is a multiple of  $n$
- ▶ **Modular Arithmetic:** Suppose  $a \equiv b \pmod{n}$ ,  $c \in \mathbb{Z}$ 
  - ▶ Addition:  $a + c \equiv b + c \pmod{n}$
  - ▶ Multiplication:  $ac \equiv bc \pmod{n}$

# Division in $\mathbb{Z}_n$

- ▶ **Definition:** Let  $a \in \mathbb{Z}$ .  $a^{-1} \in \mathbb{Z}$  is a **multiplicative inverse** of  $a$  in modulo  $n$  such that

$$a^{-1} \cdot a \equiv 1 \pmod{n}$$

- ▶ Note: We typically standardize  $a^{-1}$  to be in  $\mathbb{Z}_n$
- ▶ In modular arithmetic, dividing by  $a$  is the same as **multiplying by  $a^{-1}$**
- ▶ **WARNING:** Division is not always possible, as  $a$  does not always have an inverse
  - ▶ For example: 2 has no inverse in  $\mathbb{Z}_4 = \{0,1,2,3\}$   
 $0 \cdot 2 \equiv 2 \cdot 2 \equiv 0 \pmod{4}, 1 \cdot 2 \equiv 3 \cdot 2 \equiv 2 \pmod{4}$
- ▶ **Theorem:** An integer  $a$  has a multiplication inverse in mod  $n$  iff  **$\gcd(a, n) = 1$** 
  - ▶ **Corollary:** For all  $a \neq 0 \in \mathbb{Z}_p$ , where  $p$  is prime, there is a multiplicative inverse of  $a$  in modulo  $p$ . **-This is key in cryptography!**

# Finding Multiplicative Inverse: Intuition

- ▶ Suppose we want to find multiplicative inverse of 4 in mod 7
  - ▶ By inspection,  $\gcd(4,7) = 1$ , so 4 has multiplicative inverse in mod 7
- ▶ By definition, we want some  $b \in \mathbb{Z}$  such that
$$4b \equiv 1 \pmod{7}$$
- ▶ By definition of modular congruence,  $\exists k \in \mathbb{Z}$  such that
$$4b = 1 + 7k$$
- ▶ Rearranging,
$$4b - 7k = 1 = \gcd(4,7)$$
- ▶ **Obs:**  $b$  and  $k$  are **coefficients** of 4 and 7 in the **linear combination** of their gcd
- ▶ We have seen this in **Extended Euclid Algorithm!**

# Extended Euclid Algorithm

```
1: function EXTENDED_EUCLID( $x, y$ )
2:   if  $y = 0$  then
3:     return ( $x, 1, 0$ )
4:   else
5:     Write  $x = qy + r$  for an integer  $q$ , where  $0 \leq r < y$ 
6:      $(g, a', b') \leftarrow \text{EXTENDED\_EUCLID}(y, r)$ 
7:      $a \leftarrow b'$ 
8:      $b \leftarrow a' - b'q$ 
9:   return ( $g, a, b$ )
```

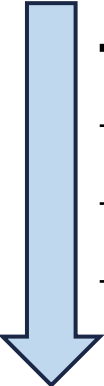

► Example: Find the multiplicative inverse of 4 in mod 7

| $x$ | $y$ | $q$ | $r$ | $g$ | $a \leftarrow b'$ | $b \leftarrow a' - b'q$ |
|-----|-----|-----|-----|-----|-------------------|-------------------------|
| 7   | 4   |     |     |     |                   |                         |
|     |     |     |     |     |                   |                         |
|     |     |     |     |     |                   |                         |
|     |     |     |     |     |                   |                         |

# Extended Euclid Algorithm

```
1: function EXTENDED_EUCLID( $x, y$ )
2:   if  $y = 0$  then
3:     return ( $x, 1, 0$ )
4:   else
5:     Write  $x = qy + r$  for an integer  $q$ , where  $0 \leq r < y$ 
6:      $(g, a', b') \leftarrow \text{EXTENDED\_EUCLID}(y, r)$ 
7:      $a \leftarrow b'$ 
8:      $b \leftarrow a' - b'q$ 
9:     return ( $g, a, b$ )
```

► Example: Find the multiplicative inverse of 4 in mod 7

| $x$ | $y$ | $q$ | $r$ | $g$ | $a \leftarrow b'$ | $b \leftarrow a' - b'q$ |
|-----|-----|-----|-----|-----|-------------------|-------------------------|
| 7   | 4   | 1   | 3   |     |                   |                         |
| 4   | 3   | 1   | 1   |     |                   |                         |
| 3   | 1   | 3   | 0   |     |                   |                         |
| 1   | 0   | -   | -   |     |                   |                         |

# Extended Euclid Algorithm

```

1: function EXTENDED_EUCLID( $x, y$ )
2:   if  $y = 0$  then
3:     return ( $x, 1, 0$ )
4:   else
5:     Write  $x = qy + r$  for an integer  $q$ , where  $0 \leq r < y$ 
6:      $(g, a', b') \leftarrow \text{EXTENDED\_EUCLID}(y, r)$ 
7:      $a \leftarrow b'$ 
8:      $b \leftarrow a' - b'q$ 
9:     return ( $g, a, b$ )

```

- Example: Find the multiplicative inverse of 4 in mod 7

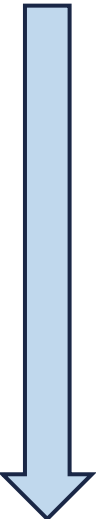

| $x$ | $y$ | $q$ | $r$ | $g$ | $a \leftarrow b'$ | $b \leftarrow a' - b'q$ |
|-----|-----|-----|-----|-----|-------------------|-------------------------|
| 7   | 4   | 1   | 3   | 1   | -1                | $1 - (-1)(1) = 2$       |
| 4   | 3   | 1   | 1   | 1   | 1                 | $0 - 1(1) = -1$         |
| 3   | 1   | 3   | 0   | 1   | 0                 | $1 - 0(3) = 1$          |
| 1   | 0   | -   | -   | 1   | 1                 | 0                       |

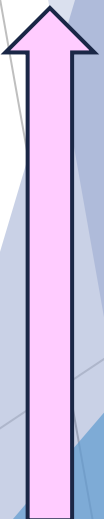

- Observe that  $4(2) - 7(-1) = 15 \equiv 1 \pmod{7}$
- In fact,  $4^{-1} \pmod{7} = 2$ 
  - Check  $2 \cdot 4 = 8 \equiv 1 \pmod{7}$

# Exercise

► Find  $13^{-1} \bmod 21$

| $x$ | $y$ | $q \leftarrow \lfloor x/y \rfloor$ | $r \leftarrow x/y - q$ | $g$ | $a \leftarrow b'$ | $b \leftarrow a' - b'q$ |
|-----|-----|------------------------------------|------------------------|-----|-------------------|-------------------------|
| 21  | 13  |                                    |                        |     |                   |                         |
|     |     |                                    |                        |     |                   |                         |
|     |     |                                    |                        |     |                   |                         |
